

The Complete Admin Panel Feature Checklist

Your admin panel isn't a side project — it's how you'll actually run the business.

THE 16 ADMIN MODULES

1. User Management · FROM THE REEL

Why you need it: Every app needs a way to see, verify, and manage the people using it — this is the foundation everything else sits on.

Without it: Support requests to "check this user" or "block that account" require a developer and a database query instead of a two-minute admin task.

Good looks like: A searchable user list with the ability to view profiles, verify accounts, and suspend or block users directly.

2. Content Management · FROM THE REEL

Why you need it: Banners, categories, and listings change constantly — tying every update to an app release is slow and unnecessary.

Without it: Every small content change (a new banner, an updated category) needs a developer and an app store release cycle to go live.

Good looks like: A CMS-style panel where non-technical team members can update content instantly, with no app update required.

3. Payments & Transactions · FROM THE REEL

Why you need it: Money is the part of the business you can least afford to manage by manually querying a database.

Without it: Refunds, failed transactions, and commission tracking become ad hoc developer requests instead of routine business operations.

Good looks like: A dashboard showing transaction status, refund tools, and commission breakdowns your finance team can use directly.

4. Notifications · FROM THE REEL

Why you need it: Reaching users directly — for offers, updates, or announcements — is core to running the business, not just a nice-to-have.

Without it: Every announcement needs an engineer to write and ship a one-off script just to message your own user base.

Good looks like: A panel to compose and send push notifications or in-app messages to all users or specific segments, on demand.

5. Reports & Exports · FROM THE REEL

Why you need it: Founders and investors ask for numbers constantly — waiting on a developer for every request doesn't scale.

Without it: Every report request becomes a distraction for your dev team, pulled away from building to write a one-time SQL query.

Good looks like: Pre-built, exportable reports (revenue, users, activity) the team can generate themselves, whenever they need them.

6. Roles & Permissions · FROM THE REEL

Why you need it: Giving every team member full access is faster to set up, but it's a liability the moment the team grows past two people.

Without it: One overwhelmed or careless team member with full access can accidentally (or deliberately) break or leak something critical.

Good looks like: Role-based access control where each team member sees and can do only what their role actually requires.

7. Order / Booking Management

Why you need it: If your app involves orders, bookings, or appointments, someone needs a way to see and manage them without touching the database.

Without it: Order issues — a stuck status, a customer dispute, a manual override — become emergency developer requests instead of routine fixes.

Good looks like: A full order/booking view with status tracking, manual overrides, and the ability to resolve disputes directly from the panel.

8. Support & Ticket Management

Why you need it: User issues need somewhere to land and get tracked, not just scattered across email, WhatsApp, and app store reviews.

Without it: Support requests get lost across channels, response times slip, and nobody has a clear view of what's actually unresolved.

Good looks like: A built-in or integrated ticketing view so support issues are logged, assigned, and tracked to resolution in one place.

9. Live Analytics Dashboard

Why you need it: Beyond exportable reports, founders need an at-a-glance view of what's happening in the business right now.

Without it: Understanding "how are we doing today" means digging through raw data or waiting for someone to pull a report.

Good looks like: A real-time dashboard surfacing key metrics — signups, revenue, active users — the moment you open the panel.

10. Audit Logs & Activity History

Why you need it: As more people get admin access, you need a record of who changed what, and when.

Without it: When something breaks or data looks wrong, there's no way to trace which team member or action caused it.

Good looks like: An activity log tracking every meaningful admin action, tied to the user who performed it and a timestamp.

11. Feature Flags & App Configuration

Why you need it: Some settings — fees, limits, toggles — change often enough that they shouldn't require a new app release each time.

Without it: Every small configuration change becomes a full development and release cycle, even for a single number or toggle.

Good looks like: A settings panel to adjust key configurations and toggle features on or off, without shipping a new app version.

12. Coupons & Discount Management

Why you need it: Marketing and growth teams need to run promotions on their own timeline, not on the dev team's release schedule.

Without it: Every promo code or discount campaign requires a developer to hardcode logic, slowing down time-sensitive marketing pushes.

Good looks like: A panel to create, schedule, and retire discount codes and promotions directly, with usage tracking built in.

13. Vendor / Partner Management

Why you need it: If your platform involves multiple vendors, sellers, or partners, someone needs to onboard, verify, and manage them centrally.

Without it: Vendor onboarding and management happen through spreadsheets and manual back-and-forth instead of a structured process.

Good looks like: A vendor management module for onboarding, verification, performance tracking, and payout management in one place.

14. Content Moderation Tools

Why you need it: Any app with user-generated content — reviews, posts, images — will eventually need to moderate what gets published.

Without it: Inappropriate or harmful content stays live because there's no efficient way to review, flag, and remove it at scale.

Good looks like: Moderation queues and flagging tools that let your team review and act on reported content quickly.

15. Session & Device Management

Why you need it: Security and support both benefit from visibility into who's logged in, from where, and on what device.

Without it: A compromised account or a user locked out of a lost device has no self-serve or admin-assisted way to be resolved quickly.

Good looks like: A panel view of active sessions and devices per user, with the ability to force logout or revoke access when needed.

16. Force-Update & App Version Control

Why you need it: Critical fixes sometimes need every user on the latest version immediately, not whenever they get around to updating.

Without it: A critical bug or security fix ships, but a portion of your user base keeps running the broken version indefinitely.

Good looks like: The ability to flag a minimum required app version and prompt or force users below it to update before continuing.

The app is what users see. The admin panel is how you actually run it.

Want an admin panel built to actually run your business, not just support the app?

We design admin panels around how your team will actually operate day to day — not as an afterthought bolted on after launch. Let's talk about your product.
